BACKUP(I)

UNIX Programmer's Manual

BACKUP(1)

NAME

backup - backup and recover files

## SYNOPSIS

backup recover [ option ... ] file ...

backup grep [ option ... ] pattern ...

backup fetch [ option ... ] [ file ... ]

backup stats [ option ... ] [ file ... ]

backup backup [ file ... ]

backup munge

backup mount [ option ... ] mountpt 2

no implemented

## DESCRIPTION

All the backup programs describe their options when presented with a bad option such as -?.

Backup recover retrieves files by name. The names should be full pathnames rooted at /n/; if not, backup tries to guess names that begin with /n/. Directories should be recovered before their contents. Regular files that are linked together will stay linked if they are recovered together. The options for recover are:

-o dir The argument is restored as an entry in the directory dir.

v Verbose (enforced).

Restore directories as files containing a null-terminated list of element names.

-r Recursively recover any subdirectories.

d Create any missing intermediate directories.

-Dold=new

Replace the prefix old of the original filename with new to form the new output filename.

-m The names are backup copy names, as determined from backup grep, not original filenames.

-fdevice

Use device rather than /dev/worm0 for the WORM. Device may be on another machine: machine!device. An initial w implies a WORM device; a j implies a jukebox. A numeric device means /dev/wormn.

-e Cause the worm fetch server on the backup system to terminate gracefully.

Append n to the output name for each file where n is an increasing integer. This is useful for recovering multiple copies of the same file.

A diagnostic like 'need disk backup2a' means you need to mount the WORM disk 'backup2a', the A side of the cartridge labeled 'backup2'.

Backup grep searches for names of backed up files that match the strings patterns. If the pattern is a literal (no -e) that looks like a filename, it reports the filename catenated with \\ and the time of the most recent backup copy. If the pattern is a literal that looks like the output under option -d, it reports the name of the corresponding backup copy. The options are:

- Print file change times (ctime, see stat(2)) as integers rather than as dates.
- -e Interpret patterns as regular expressions given in the notation of regexp(3). Warning: this option can execute extremely slowly; you may be better off using gre(1) on on the backup machine; see backup(5).
- -a Print all names in the database.
- Treat pattern as a literal filename and list all versions of the file.
- Only list entries with a date less than or equal to n. If n is not a simple integer date, it is interpreted as by timec(3).

->n Only list entries with a date greater than or equal to n.

-D Print the most recent entry for every file name starting with pattern, taking into account any cutoff date, but turning off option -e.
